# **Operating System**

Lecture 14: Virtual Memory

Manoj Kumar Jain

M.L. Sukhadia University Udaipur

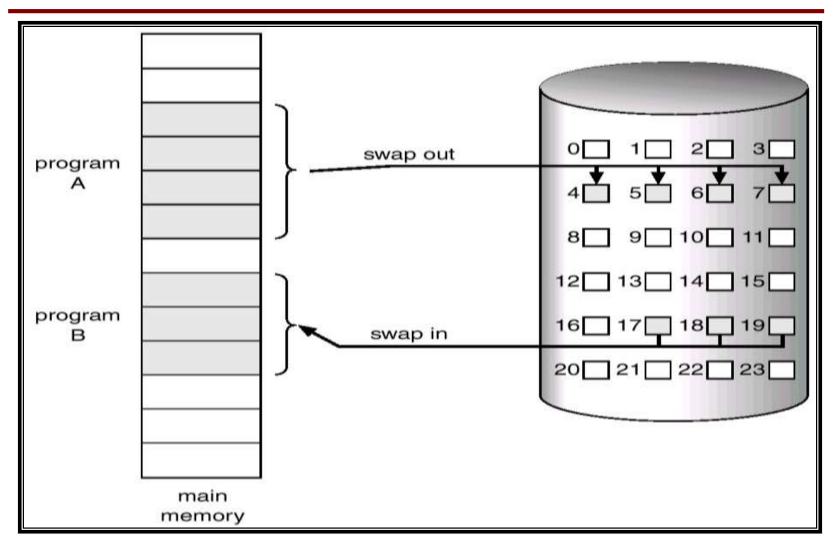

#### Chapter 10: Virtual Memory

- Demand Paging
- Page Replacement
- Thrashing

#### **Demand Paging**

- Bring a page into memory only when it is needed.
  - Less I/O needed
  - Less memory needed
  - Faster response
  - More users
- Page is needed ⇒ reference to it
  - invalid reference ⇒ abort
  - not-in-memory ⇒ bring to memory

#### Transfer of a Paged Memory to Contiguous Disk Space

#### Valid-Invalid Bit

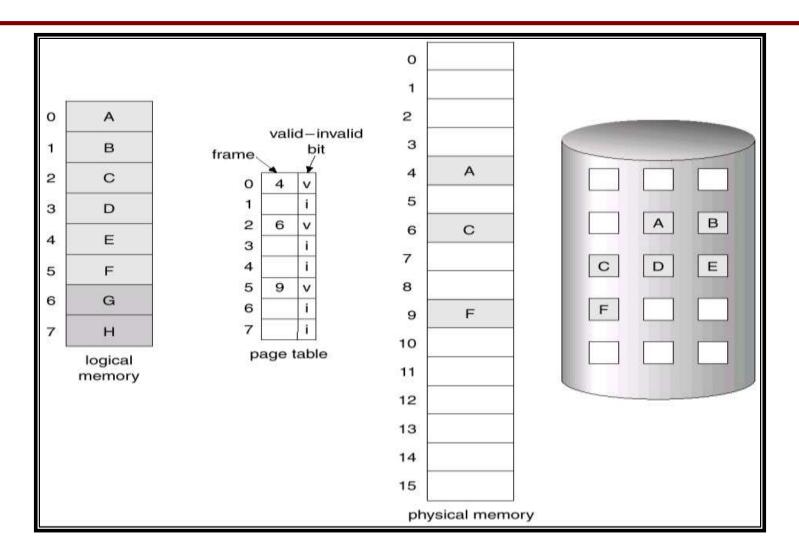

- With each page table entry a valid—invalid bit is associated  $(1 \Rightarrow \text{in-memory}, 0 \Rightarrow \text{not-in-memory})$
- Initially valid—invalid but is set to 0 on all entries.
- Example of a page table snapshot.

Frame #	valic	d-invalid bit
	1	
	1	
	1	
	1	
	0	
:		
•		
	0	
	0	

page table

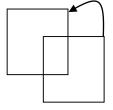

During address translation, if valid—invalid bit in page table entry is

#### Page Table When Some Pages Are Not in Main Memory

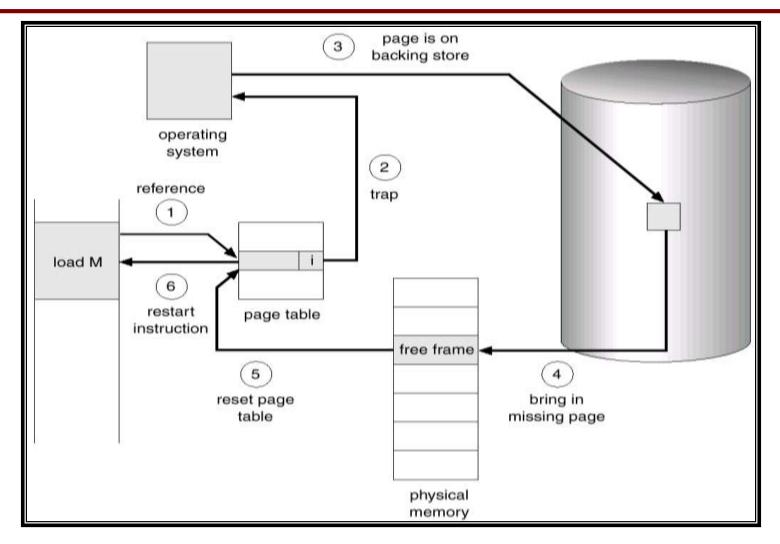

#### Page Fault

- If there is ever a reference to a page, first reference will trap to OS ⇒ page fault
- OS looks at another table to decide:
  - Invalid reference ⇒ abort.
  - Just not in memory.
- Get empty frame.
- Swap page into frame.
- Reset tables, validation bit = 1.
- Restart instruction: Least Recently Used
  - block move

auto increment/decrement location

# Steps in Handling a Page Fault

#### What happens if there is no free frame?

- Page replacement find some page in memory, but not really in use, swap it out.
  - algorithm
  - performance want an algorithm which will result in minimum number of page faults.
- Same page may be brought into memory several times.

# Performance of Demand Paging

- Page Fault Rate  $0 \le p \le 1.0$ 
  - if p = 0 no page faults
  - $\blacksquare$  if p = 1, every reference is a fault
- Effective Access Time (EAT)
  - $EAT = (1 p) \times memory access$ 
    - + p (page fault overhead
    - + [swap page out ]
    - + swap page in
    - + restart overhead)

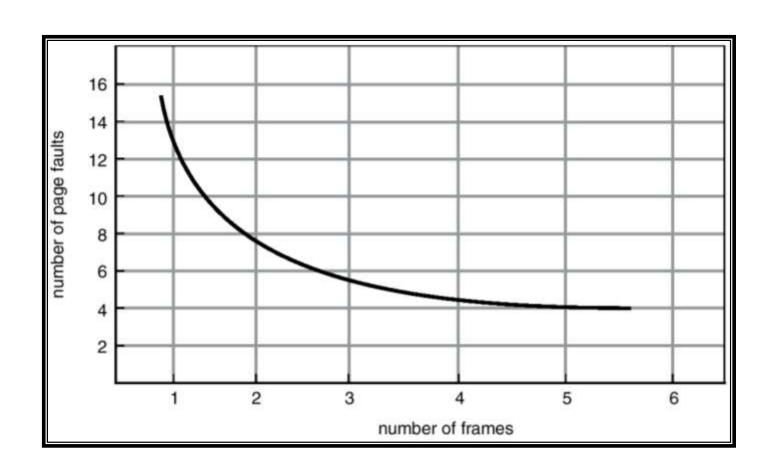

#### Demand Paging Example

- Memory access time = 1 microsecond
- 50% of the time the page that is being replaced has been modified and therefore needs to be swapped out.
- Swap Page Time = 10 msec = 10,000 msec  $EAT = (1 - p) \times 1 + p (15000)$ 1 + 15000P (in msec)

#### Page Replacement Algorithms

- Want lowest page-fault rate.
- Evaluate algorithm by running it on a particular string of memory references (reference string) and computing the number of page faults on that string.
- In all our examples, the reference string is 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5.

#### Graph of Page Faults Versus The Number of Frames

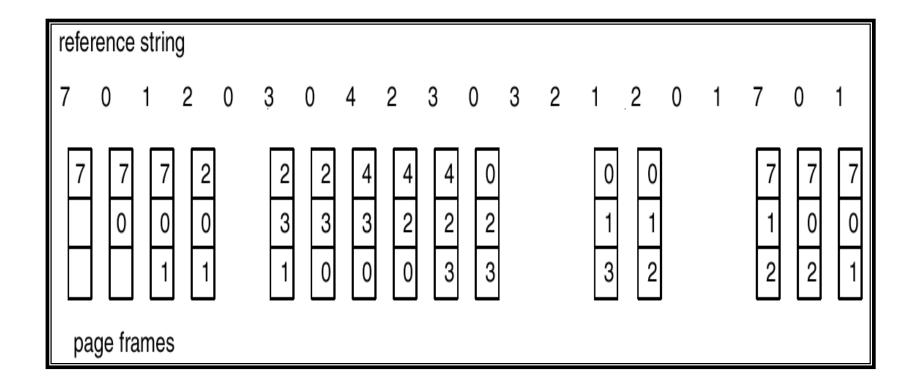

#### First-In-First-Out (FIFO) Algorithm

- Reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5
- 3 frames (3 pages can be in memory at a time per process)

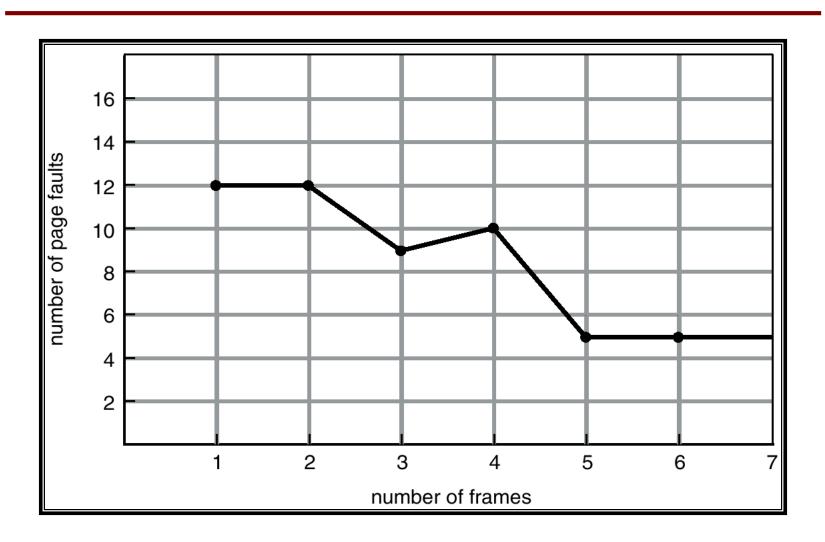

4 frames

- FIFO Replacement Belady's Anomaly
  - $\blacksquare$  more frames  $\Rightarrow$  less page faults

# FIFO Page Replacement

# FIFO Illustrating Belady's Anamoly

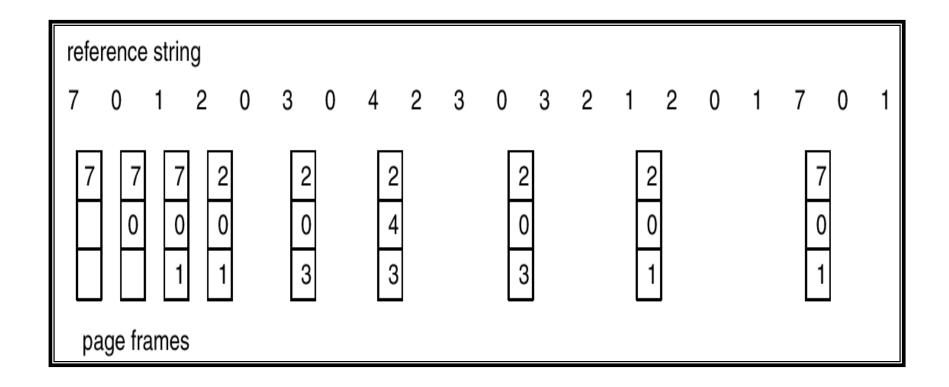

#### **Optimal Algorithm**

- Replace page that will not be used for longest period of time.
- 4 frames example

1	4	
2		6 page faults
3		
4	5	

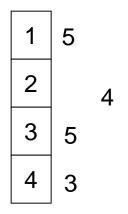

- How do you know this?
- Used for measuring how well your algorithm performs.

# Optimal Page Replacement

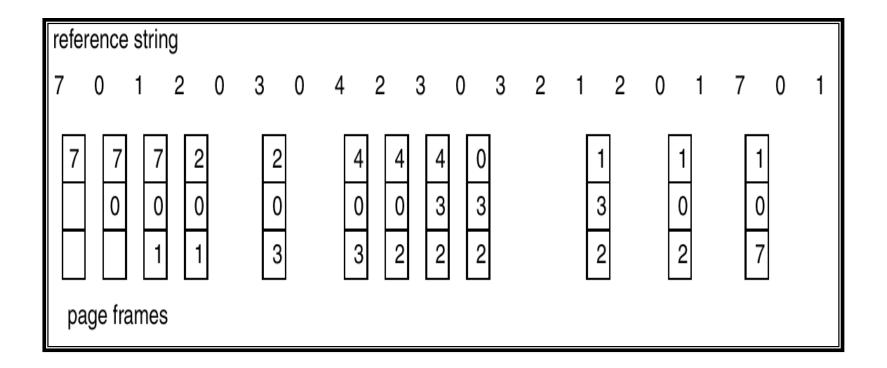

# Least Recently Used (LRU) Algorithm

Reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5

- Counter implementation
  - Every page entry has a counter; every time page is referenced through this entry, copy the clock into the counter.
  - When a page needs to be changed, look at the counters to determine which are to change.

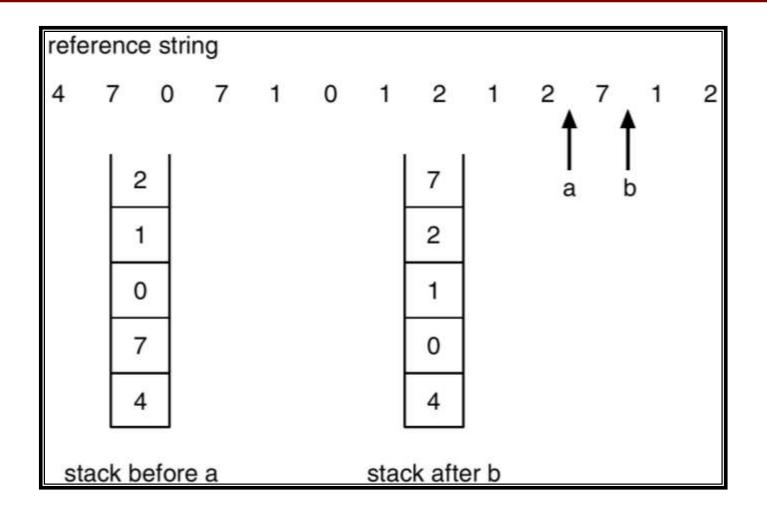

#### LRU Page Replacement

# LRU Algorithm (Cont.)

- Stack implementation keep a stack of page numbers in a double link form:
  - Page referenced:
    - move it to the top
    - requires 6 pointers to be changed
  - No search for replacement

#### Use Of A Stack to Record The Most Recent Page References

#### LRU Approximation Algorithms

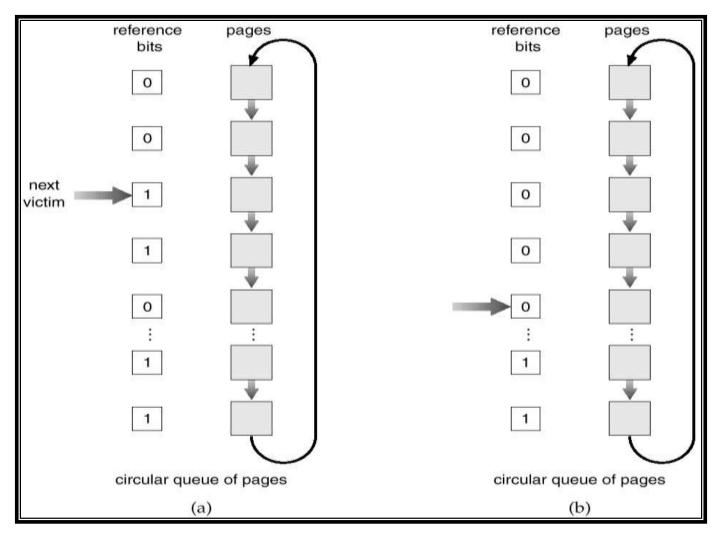

#### Reference bit

- With each page associate a bit, initially = 0
- When page is referenced bit set to 1.
- Replace the one which is 0 (if one exists). We do not know the order, however.

#### Second chance

- Need reference bit.
- Clock replacement.
- If page to be replaced (in clock order) has reference bit = 1. then:
  - set reference bit 0.
  - leave page in memory.
  - replace next page (in clock order), subject to same rules.

#### Second-Chance (clock) Page-Replacement Algorithm

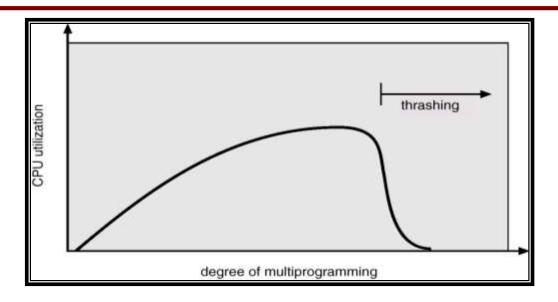

#### Counting Algorithms

- Keep a counter of the number of references that have been made to each page.
- LFU Algorithm: replaces page with smallest count.
- MFU Algorithm: based on the argument that the page with the smallest count was probably just brought in and has yet to be used.

#### Thrashing

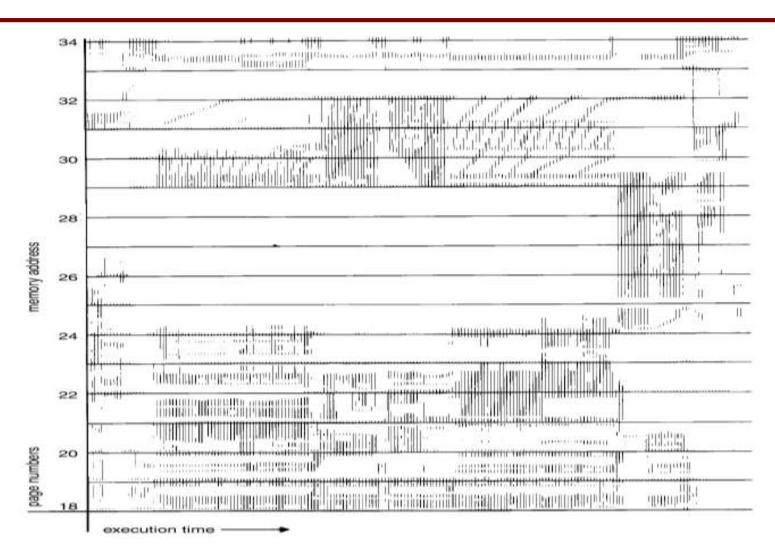

- If a process does not have "enough" pages, the page-fault rate is very high. This leads to:
  - low CPU utilization.
  - operating system thinks that it needs to increase the degree of multiprogramming.
  - another process added to the system.
- Thrashing = a process is busy swapping pages in and out.

# **Thrashing**

- Why does paging work? Locality model
  - Process migrates from one locality to another.
  - Localities may overlap.
- Why does thrashing occur?
   Σ size of locality > total memory size

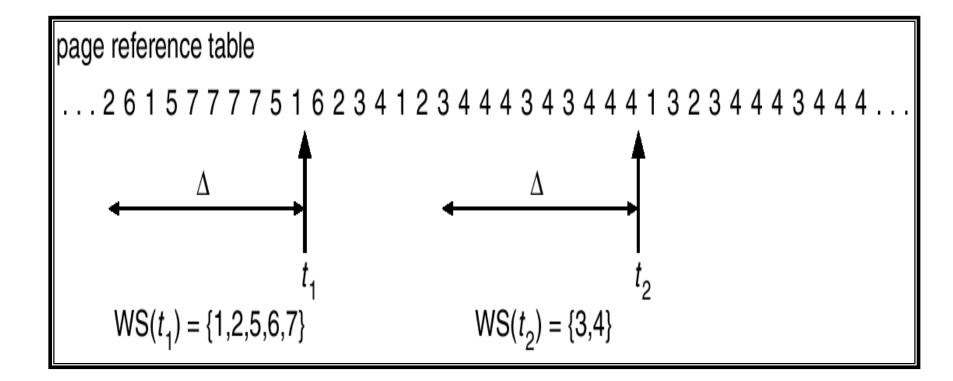

#### Locality In A Memory-Reference Pattern

# Working-Set Model

- $\Delta \equiv$  working-set window  $\equiv$  a fixed number of page references
  - Example: 10,000 instruction
- $WSS_i$  (working set of Process  $P_i$ ) = total number of pages referenced in the most recent  $\Delta$  (varies in time)
  - lacktriangle if  $\Delta$  too small will not encompass entire locality.
  - if  $\Delta$  too large will encompass several localities.
  - if  $\Delta = \infty \Rightarrow$  will encompass entire program.
- $D = \sum WSS_i \equiv \text{total demand frames}$
- if  $D > m \Rightarrow$  Thrashing
- Policy if D > m, then suspend one of the processes.

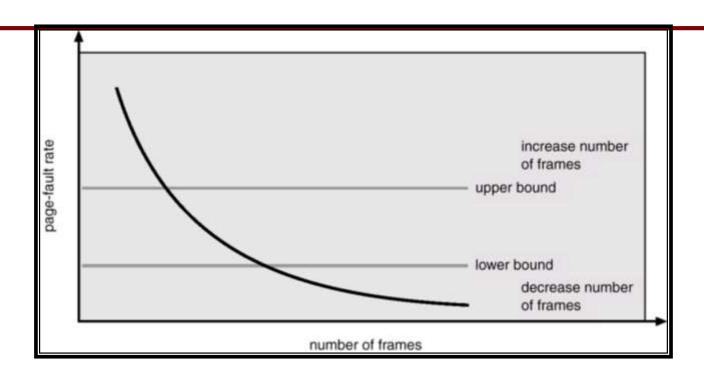

#### Working-set model

#### Keeping Track of the Working Set

- Approximate with interval timer + a reference bit
- Example:  $\Delta = 10,000$ 
  - Timer interrupts after every 5000 time units.
  - Keep in memory 2 bits for each page.
  - Whenever a timer interrupts copy and sets the values of all reference bits to 0.
  - If one of the bits in memory =  $1 \Rightarrow$  page in working set.
- Why is this not completely accurate?
- Improvement = 10 bits and interrupt every 1000 time units.

#### Page-Fault Frequency Scheme

- Establish "acceptable" page-fault rate.
  - If actual rate too low, process loses frame.
  - If actual rate too high, process gains frame.

#### Other Considerations

- Prepaging
- Page size selection
  - fragmentation
  - table size
  - I/O overhead
  - locality

# Other Considerations (Cont.)

**TLB Reach** - The amount of memory accessible from the TLB.

- TLB Reach = (TLB Size) X (Page Size)
- Ideally, the working set of each process is stored in the TLB. Otherwise there is a high degree of page faults.

#### Increasing the Size of the TLB

- Increase the Page Size. This may lead to an increase in fragmentation as not all applications require a large page size.
- Provide Multiple Page Sizes. This allows applications that require larger page sizes the opportunity to use them without an increase in fragmentation.

#### Other Considerations (Cont.)

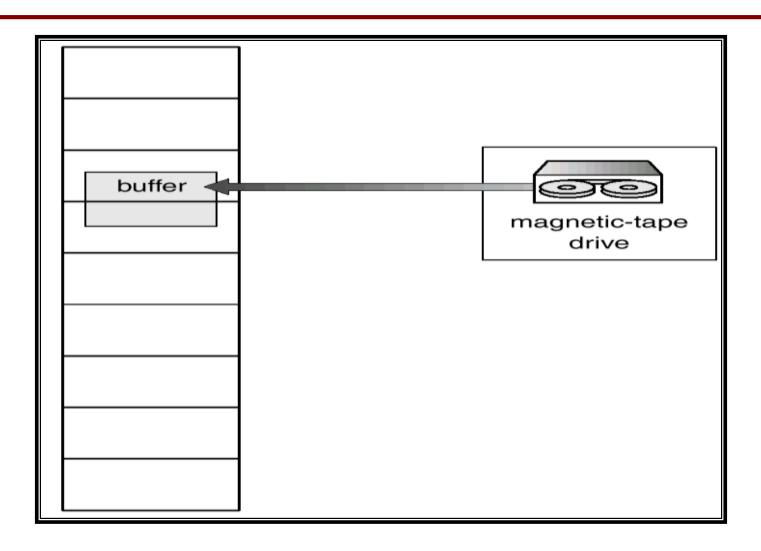

- Program structure
  - int A[][] = new int[1024][1024];
  - Each row is stored in one page
  - Program 1 for (j = 0; j < A.length; j++) for (i = 0; i < A.length; i++) A[i,j] = 0; 1024 x 1024 page faults</p>
  - Program 2 for (i = 0; i < A.length; i++) for (j = 0; j < A.length; j++) A[i,j] = 0;

1024 page faults (assuming page size 1024 words)

# Other Considerations (Cont.)

- I/O Interlock Pages must sometimes be locked into memory.
- Consider I/O. Pages that are used for copying a file from a device must be locked from being selected for eviction by a page replacement algorithm.

#### Reason Why Frames Used For I/O Must Be In Memory

# Thanks
